## 2.2 Rooshan Khan: Attention Method in bert.py

In this method we had to implement Attention method from class BertSelfAttention. The attention mechanism is given by:

$$Attention(Q, K, V) = softmax(\frac{QK^{T}}{\sqrt{d_k}})V$$
 (1)

where Q, K, and V represent the query, key, and value matrices, respectively, and  $d_k$  is the dimension of the key vectors.

I used method torch.matmul to multiply Q and transpose of K. I multiplied the result with  $attention\_mask$  to apply the mask. The dimensions of attention\\_mask are  $[bs, 1, 1, seq\_len]$ . The attention mask distinguishes between non-padding tokens and padding tokens. The non-padding tokens have a value of 0 while padding tokens have a value of a large negative number. The dimensions of key\_layer, query\_layer and value\_layer are  $[bs, num\_attention\_heads, seq\_len, attention\_head\_size]$ 

Now I will tell how I concatenated all heads. When we transpose the tensor we change the shape of the tensor from [bs,num\_attention\_heads, seq\_len, attention\_head\_size] to [bs,seq\_len,num\_attention\_heads, attention\_head\_size]. This enables us to reshape the tensor to [bs,seq\_len,num\_attention\_heads \* attention\_head\_size]. After applying the transpose method the data sequence does not follow a contiguous order so we need to use **contiguous** method before using the **view** method.
